

F_a applied force
(just a catch-all term
for when you try
and push or pull something)

F_T tension
(the force in a string)
• strings can only pull an object - you
can't push something with a string

Some Less Common Forces

F_d Drag Force - the name for air resistance.

F_L Lift Force - with planes & helicopters, this is
the aerodynamics force from the
wings that "lifts" the plane
off the ground.

F_t Thrust - the force from a plane or rocket
engine

Back to The Cow $\hat{=}$ more examples

Now imagine there is a wind trying to push the cow to the right. Because it is standing on the ground, the cow doesn't move - because FRICTION will hold it in place.

everything is still balanced!
everything still cancels out!

A car driving to the right @ constant speed.

everything balanced!
all the forces cancel -
so constant speed

F_a - the applied force, which comes from the engine $\hat{=}$ tires

F_d - drag force trying to slow the car down.

If $F_a > F_d$ the car would speed up

If $F_a < F_d$ the car would slow down

When all the forces cancel out, we say the NET FORCE is zero.

F_{net} Net Force \rightarrow what's leftover after adding & subtracting all the forces acting on an object.

$F_{\text{net}} = 0$ all the forces cancel out.
all the forces are balanced.

$\therefore F_{\text{net}} = 0 \iff \text{constant velocity!}$
(acceleration = 0)
